Create a small project that gets data from a remote API and shows them inside a list.

The goal of this project is get the data about film reviews from the New York Times API.

After you have created and account to get access to the mentioned API you will have to use the Movie Reviews API.

The data has to be filtered by the critics' pick and sorted by publication date. For each result we need to display the title of the movie, the short summary of the review and the image associated with it. Each item will have the link to the full review (which will point to NYT itself).
Using Angular will have to get a reply from the NYT's API and the populate the index page that you will find on the repo using the "service_blog" card as a template.

Once done create a new branch on the repo and push the files on it
